Reacting elements with oxygen

Introduction
Many elements react with oxygen. The ease with which the reaction takes place, the vigour of the reaction and the properties of the compounds made provide excellent evidence to help understanding about the periodic nature of the elements in the Periodic Table and about many chemical principles. The difference in reactivity between reactions in air and in oxygen can be related to the relative concentrations.

Equipment
Apparatus
- Eye protection
- Fume cupboard
- Gas preparation apparatus
- Side-arm flask, 250 cm$^3$
- Tap funnel and bung to fit flask
- Connecting tubing
- Reaction tubes, one for each reaction
- 1-hole bung and delivery tube to fit
- Clamp stand
- Boss head
- Clamp

Chemicals
- Hydrogen peroxide solution, 15 cm$^3$ 20 vol per experiment
- Manganese(IV) oxide granular, 5 g
- Lithium
• Sodium
• Potassium
• Magnesium
• Calcium
• Aluminium foil
• Carbon
• Phosphorous red
• Sulfur

Health, safety and technical notes
• Read our standard health and safety guidance here https://rsc.li/3FiTQXc
• Wear eye protection at all times.
• It is recommended that these experiments are done by the demonstrator before
  demonstrating to pupils, in order to gain experience, if they have not done it before.
• Group 1 metals are stored under oil, this can be removed using paper tissue.
• Cut pieces of Group 1 metals into cubes no bigger than 3 mm.
• For other elements, 0.1g is sufficient to see a reaction.
• Lithium, sodium and potassium are all highly flammable and corrosive (see
  CLEAPSS Hazcards - HC058a, HC088, HC076).
• Magnesium, calcium and phosphorous red are all highly flammable (see CLEAPSS
  Hazcards HC059a, HC016, HC073b).
• Aluminium foil, carbon, and sulfur are all low hazard (see CLEAPSS
  Hazcards HC001a, HC021, HC096a).

Procedure
1. The apparatus is assembled in a fume cupboard, according to the diagram provided.
2. A reaction tube is clamped horizontally close to the bung end.
3. The tubes are used to connect the gas generator to the delivery tube in the bung.
4. A piece of the element is placed near the bottom of the test tube.
5. The bung is pushed gently into the reaction tube.
6. Start the oxygen gas generation by running hydrogen peroxide onto the catalyst. Use
   1. 20 cm3 hydrogen peroxide solution to flush the system of air for 60 seconds.
7. Heat the solid element using a Bunsen burner with a blue flame.
8. Add more hydrogen peroxide slowly.
9. Remove the Bunsen burner when the element catches fire.

Notes
• The synthesis reactions of these binary compounds (two elements) will catch the
  attention of students because they are spectacular.
• Group 1 and 2 – Students see the increase in reactivity going down the group
  (inferred from the heating time required).
• They will see the reaction start when the metal begins to melt. Melting allows fresh
  metal to flow out from under the oxide coating which inevitably forms on the surface
  of metals.
• Students understand why metals start to react vigorously with gases when they melt.
• They will not appreciate that most combustion reactions do not involve solids.
• The temperature of reaction and the melting points of elements can be related to
  their structure and bonding.
• Carbon and silicon burn in the solid state, unlike the other elements.
• The melting points, reaction with water and pH of the solutions of these compounds
  are all logical developments of this topic.
